digital futures

Today:

(i) Are dynamical systems that render a set *asymptotically stable, homotopic* through dynamical systems that preserve this notion of stability?

(ii) When is a *closed* attractor, on a metric space, homotopy equivalent to its basin of attraction?

Context?

In the beginning (e.g., see [Maw94; LP17]): Poincaré and Lyapunov.

1892 was a good year:

- H. Poincaré, *Les méthodes nouvelles de la mécanique céleste* (I) (1892).
- A. M. Lyapunov, *The general problem of the stability of motion* (PhD thesis) (1892).

First formal study into stability of motion due to Lagrange, through potential energy. (Although Lagrange stability should be called Dirichlet stability..)

Consider $\dot{x} = f(x)$ with $x \in \mathbb{R}^n$, then (x_1, \dots, x_n, t) was called the **motion space**. Lyapunov speaks of **stability** when for any $\varepsilon > 0$ we can find a $\delta > 0$ such that solutions $x(t)$ starting in B_δ stay in B_ε .

Then, 0 is *Lyapunov stable* if there is a $V \in C^1(\mathbb{R}^n; \mathbb{R}_{\geq 0})$ with $V(0) = 0$, such that $V' \leq 0$. We speak of **asymptotic stability** when $V' < 0$, i.e., $\lim_{t \rightarrow \infty} x(t) = 0$.

Further developments by Četeav, Barbashin, Krasovskii, ... (inControl podcast!)

asymptotic stability = stability (a) + attractivity (b).

asymptotic stability = stability (a) + attractivity (b).

(i): motivated by questions of *stabilization*, not only stability.

asymptotic stability = stability (a) + attractivity (b).

(i): motivated by questions of *stabilization*, not only stability.

Not only *describe* a solution to $\dot{x} = f(x)$,
but rather *prescribe* the dynamics of $\dot{x} = f(x, u)$ through a choice of input u .

A coarse view on stabilization: the Krasnosel'skiĭ-Zabreĭko (Bobylev) theorem

Theorem (Index of asymptotically stable equilibrium points [Kra68, Ch. II], [KZ84, Thm. 52.1].)

Let $p^* \in M^n$ be an isolated **asymptotically stable** equilibrium point of $X \in \Gamma^r(TM^n)$. Then,
 $\text{ind}_{p^*}(X) = (-1)^n$.

¹For **continuous** locally asymptotic stabilization of a point.

A coarse view on stabilization: the Krasnosel'skiĭ-Zabreĭko (Bobylev) theorem

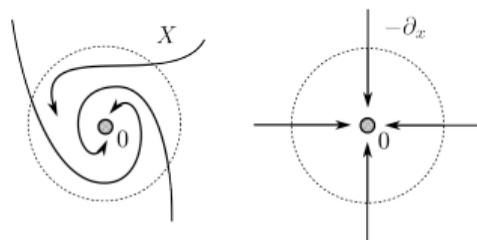

Theorem (Index of asymptotically stable equilibrium points [Kra68, Ch. II], [KZ84, Thm. 52.1].)

Let $p^* \in M^n$ be an isolated **asymptotically stable** equilibrium point of $X \in \Gamma^r(TM^n)$. Then, $\text{ind}_{p^*}(X) = (-1)^n$.

Proof sketch: In coordinates, $p^* = 0 \in \mathbb{R}^n$, $\text{ind}(\cdot)$ is a *homotopy invariant*. Details in (J. and Moulay Springer23).

$X \simeq_h$ (loc.) $-\partial_x$ ("canonical" system),
without introducing new zeroes

¹For **continuous** locally asymptotic stabilization of a point.

A coarse view on stabilization: the Krasnosel'skiĭ-Zabreĭko (Bobylev) theorem

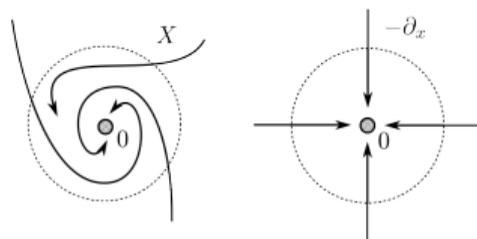

Theorem (Index of asymptotically stable equilibrium points [Kra68, Ch. II], [KZ84, Thm. 52.1].)

Let $p^* \in M^n$ be an isolated **asymptotically stable** equilibrium point of $X \in \Gamma^r(TM^n)$. Then, $\text{ind}_{p^*}(X) = (-1)^n$.

Proof sketch: In coordinates, $p^* = 0 \in \mathbb{R}^n$, $\text{ind}(\cdot)$ is a *homotopy invariant*. Details in (J. and Moulay Springer23).

$X \simeq_h$ (loc.) $-\partial_x$ ("canonical" system),
without introducing new zeroes

Ramification: for $\dot{x} = f(x, u)$ (C^0), a *necessary* condition for the existence of continuous, stabilizing feedback is $\exists \mu \in C^0 : \text{ind}_0(f(\cdot, \mu(\cdot))) = (-1)^n$.

¹For *continuous* locally asymptotic stabilization of a point.

A coarse view on stabilization: the Krasnosel'skiĭ-Zabreĭko (Bobylev) theorem

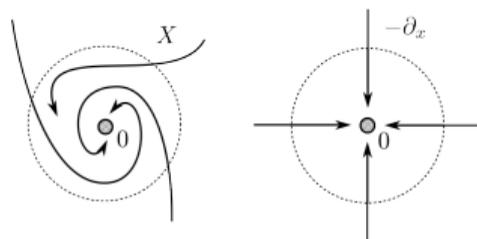

Theorem (Index of asymptotically stable equilibrium points [Kra68, Ch. II], [KZ84, Thm. 52.1].)

Let $p^* \in M^n$ be an isolated **asymptotically stable** equilibrium point of $X \in \Gamma^r(TM^n)$. Then,

Proof sketch: In coordinates, $p^* = 0 \in \mathbb{R}^n$, $\text{ind}(\cdot)$ is a **homotopy invariant**. Details in (J. and Moulay Springer23).

$X \simeq_h$ (loc.) $-\partial_x$ ("canonical" system),
without introducing new zeroes

Ramification: for $\dot{x} = f(x, u)$ (C^0), a *necessary* condition for the existence of continuous, stabilizing feedback is $\exists \mu \in C^0 : \text{ind}_0(f(\cdot, \mu(\cdot))) = (-1)^n$. Implies "all" well-known topological obstructions¹ (due to Zabczyk), e.g., $(x, u) \mapsto f(x, u)$ must map $W \ni (0, 0)$ onto $V \ni 0$ (Brockett).

¹For **continuous** locally asymptotic stabilization of a point.

Application (*sketch*):

Implies “all” well-known topological obstructions² (due to Zabczyk), e.g., $(x, u) \mapsto f(x, u)$ must map neighbourhood $W \ni (0, 0)$ **onto** neighbourhood $V \ni 0$ (Brockett).

Consider the control system (topologically equivalent to a unicycle/‘car’):

$$\begin{aligned} \dot{x}_1 &= u_1 \\ \dot{x}_2 &= u_2 \\ \dot{x}_3 &= x_2 u_1 - x_1 u_2, \end{aligned} \quad \equiv \quad \dot{x} = g_1(x)u_1 + g_2(x)u_2 \quad (1)$$

Can we find a C^0 feedback $(x \mapsto (u_1(x), u_2(x)))$ such that 0 is stabilized?

- (1) is *controllable* as $\text{span}\{g_1, g_2, [g_1, g_2]\} = \mathbb{R}^3$ [NS90]. You can park your car!
- But, Brockett’s condition [Bro83] fails, no solution to $f(x, u) = (0, 0, \varepsilon)$, $\varepsilon > 0$. So, no.

²For **continuous** locally asymptotic stabilization of a point.

Application (*sketch*):

Implies “all” well-known topological obstructions² (due to Zabczyk), e.g., $(x, u) \mapsto f(x, u)$ must map neighbourhood $W \ni (0, 0)$ **onto** neighbourhood $V \ni 0$ (Brockett).

Consider the control system (topologically equivalent to a unicycle/’car’):

$$\begin{aligned} \dot{x}_1 &= u_1 \\ \dot{x}_2 &= u_2 \\ \dot{x}_3 &= x_2 u_1 - x_1 u_2, \end{aligned} \quad \equiv \quad \dot{x} = g_1(x)u_1 + g_2(x)u_2 \quad (1)$$

Can we find a C^0 feedback $(x \mapsto (u_1(x), u_2(x)))$ such that 0 is stabilized?

- (1) is **controllable** as $\text{span}\{g_1, g_2, [g_1, g_2]\} = \mathbb{R}^3$ [NS90]. You can park your car!

²For *continuous* locally asymptotic stabilization of a point.

Motivation from index theory, cont'd

“To what extent does the homotopy index [Conley index] itself determine the equivalence class of isolated invariant sets which are related by continuation?” [Con78, p. 83].

In general, the answer is *no* [MRS00],
but we can study:

Question: “Are dynamical systems that render a set A asymptotically stable, homotopic through dynamical systems that preserve this notion of stability?”

Differently put, can we strengthen the result by Krasnosel'skiĭ?

Partial answer to (i)

Theorem (Existence of a stability preserving homotopy, WJ 26.³)

For any two vector fields X, Y , rendering some $p^ \in M$ globally asymptotically stable (GAS), there is a homotopy between the corresponding semiflows $\varphi(\cdot; X)$ and $\varphi(\cdot; Y)$ such that p remains GAS along the homotopy.*

(recently, big leap by Kvalheim [Kva25].) Cruc: 'homotope' everything to $\dot{x} = -x$.

³WJ, "Asymptotic stability equals exponential stability—while you twist your eyes," 2026. *Systems & Control Letters*. Indeed, homage to [GSW99]: Grüne, Sontag and Wirth, "Asymptotic stability equals exponential stability, and ISS equals finite energy gain—if you twist your eyes," 1999. *Systems & Control Letters*. See also: WJ and Roland Schwan, 2024. *IEEE TAC*.

Inspired by Morse theory, the proof proceeds as:

(0) Let X be the vector field and V a C^∞ Lyapunov function, then, 'homotope' $\varphi^\tau(\cdot; X)$ to $\varphi^\tau(\cdot; -\nabla V)$, e.g., use $(1-s)X - s\nabla V$, with $s \in [0, 1]$.

(1) Extend [GSW99]: show that for all $\gamma \in \mathcal{K}_\infty$,⁴ there is a $T \in \text{Homeo}^+(\mathbb{R}^n; \mathbb{R}^n)$ (not just $T \in \text{Homeo}(\mathbb{R}^n; \mathbb{R}^n)$) such that $V(T^{-1}(x)) = \gamma(\|x\|_2)$.

(i) As $V^{-1}(c) \simeq_h S^{n-1}$, there is a homeomorphism
 $S : V^{-1}(c) \rightarrow S^{n-1}$.

(ii) $T : \mathbb{R}^n \rightarrow \mathbb{R}^n$ via $T(0) = 0$, otherwise
 $T(x) = \gamma^{-1}(V(x)) S \circ \pi_c$.⁵

(iii) Now, keep S , or flip a coordinate (flip the sign of the degree).

⁴ $\gamma : \mathbb{R}_{\geq 0} \rightarrow \mathbb{R}_{\geq 0}$ is strictly monotone, C^0 , $\gamma(0) = 0$ and $\lim_{s \rightarrow +\infty} \gamma(s) = +\infty$.

⁵Let ψ be the local flow corresponding to $\dot{x} = \nabla V(x) / \|\nabla V(x)\|_2^2$, fix some $c > 0$ and define $\pi_c : \mathbb{R}^n \setminus \{0\} \rightarrow V^{-1}(c)$ through $\pi_c(x) := \psi(c - V(x), x)$. See that $V(\psi(t, x)) = V(x) + t$.

Inspired by Morse theory, the proof proceeds as:

(2) T^{-1} can be shown to be homotopic to $\text{id}_{\mathbb{R}^n}$ along a continuous path in $\text{Homeo}^+(\mathbb{R}^n; \mathbb{R}^n)$ (*Stable Homeomorphism Theorem*, Kirby).

(3) Use (1) and (2) to homotope $\varphi^\tau(\cdot; -\nabla V)$ to a semiflow, denoted $\tilde{\varphi}^\tau(\cdot)$, that has $V(T^{-1}(x))$ as its Lyapunov function. 0 remains GAS along the path. Next, exploit the simple form of $V(T^{-1}(x))$.

(4) Along the homotopy from T^{-1} to $\text{id}_{\mathbb{R}^n}$, smoothness is not understood, but at T , it is, for some γ . Hence, we can consider the vector field (on $\mathbb{R}^n \setminus \{0\}$) corresponding to $\tilde{\varphi}$ (and homotope to $-\partial_x$):

$$\left. \frac{d}{dt} \tilde{\varphi}^t(x) \right|_{t=0} = -DT(T^{-1}(x)) \nabla V(T^{-1}(x)).$$

(DT?)

Proof cont'd:

(1) Extend [GSW99]: show that $\forall \gamma \in \mathcal{K}_\infty$ there is a $T \in \text{Homeo}^+(\mathbb{R}^n; \mathbb{R}^n)$ (not just $T \in \text{Homeo}(\mathbb{R}^n; \mathbb{R}^n)$) such that $V(T^{-1}(x)) = \gamma(\|x\|_2)$.

(2) T^{-1} can be shown to be homotopic to $\text{id}_{\mathbb{R}^n}$ along a continuous path in $\text{Homeo}^+(\mathbb{R}^n; \mathbb{R}^n)$ (*Stable Homeomorphism Theorem*, Kirby).

(3) Use (1) and (2) to homotope $\varphi^\tau(\cdot; -\nabla V)$ to a semiflow, denoted $\tilde{\varphi}^\tau(\cdot)$, that has $V(T^{-1}(x))$ as its Lyapunov function. 0 remains GAS along the path. Next, exploit the simple form of $V(T^{-1}(x))$.

(4) Along the homotopy from T^{-1} to $\text{id}_{\mathbb{R}^n}$, smoothness is not understood, but at T , it is, for some γ . Hence, we can consider the vector field (on $\mathbb{R}^n \setminus \{0\}$) corresponding to $\tilde{\varphi}$ (and homotope to $-\partial_x$):

$$\left. \frac{d}{dt} \tilde{\varphi}^t(x) \right|_{t=0} = -DT(T^{-1}(x)) \nabla V(T^{-1}(x)).$$

(DT?)

The smooth Poincaré conjecture and DT .

Wilson [Wil67]: $V^{-1}(c) \simeq_h \mathbb{S}^{n-1}$, can we go beyond *homotopy equivalence*? To construct T in Item 4 we use the existence of a **diffeomorphism** $S : V^{-1}(c) \rightarrow \mathbb{S}^{n-1}$. ($V^{-1}(c)$ is a Lyapunov level set.)

Generalized Poincaré conjecture:

every homotopy m -sphere is C -isomorphic to \mathbb{S}^m , $C = \{\text{Top, PL, Diff}\}$.

True for Top (concluded by Perelman), for Diff true for, e.g., $m = 1, 2, 3, 5, 6$, known to fail for $m = 7$ (Milnor's exotic spheres).

However, $V^{-1}(c)$ is not *any* set, for $m \geq 5$, we can appeal to Smale's h-cobordism theorem.

$m = 4$ recently resolved via work by Kvalheim and Sontag [KS25].

A lot can be said about equilibria on \mathbb{R}^n , what about more general attractors⁶?
(ii): In particular, given an attractor A on a space X , could it be a *global* attractor?

⁶For more motivation, background and results, see: WJ and Emmanuel Moulay, “Topological Obstructions to Stability and Stabilization: History, Recent Advances and Open Problems”, 2023. Springer

Lyapunov theory beyond equilibria.

Stability: from a bouncing ball.. to slushing coffee.., under sufficiently small perturbations, the 'state' of our system returns to a certain 'steady-state'.. ..we need a general theory.

Conley: let (X, d) be a compact (why?) metric space and φ a flow on X , then, $A \subseteq X$ is an attractor if there is a $U \supseteq A$ such that $\omega(U) = A$ (omega limit set). Let A^* be the (dual) repeller.

Define the C^0 (!) functions:

$$f(x) := \frac{d(x, A)}{d(x, A) + d(x, A^*)} \quad \text{and} \quad g(x) := \sup_{t \geq 0} \{f(\varphi(x, t))\}.$$

It follows that $g^{-1}(0) = A$, $g^{-1}(1) = A^*$ and $g(\varphi(x, t)) \leq g(x)$. Now, pick $x \in X \setminus \{A \cup A^*\}$ and define

$$V(x) := \int_0^\infty e^{-\tau} g(\varphi(x, \tau)) d\tau, \quad \text{then } V^{-1}(0) = A, V^{-1}(1) = A^*$$

and $V(x) - V(\varphi(x, t)) \geq 0$, with ' $= 0$ ' $\iff g(\varphi(x, \tau)) = g(\varphi(x, t + \tau)) \forall t \geq 0$. But then, $x \in A \cup A^*$.

We have found a C^0 map $V : X \rightarrow [0, 1]$ capturing 'the convergence to A ', i.e., a Lyapunov function.

But $\omega(U) = A$? Does it always suffice?

Without compactness, what can be done?

Despite pioneering work by [Bhatia†](#) et al., Lyapunov theory is not 'finished' for semiflows.

Let A be an **attractor*** under a semiflow on X . For the following settings there is a 'complete' Lyapunov theory:

(L) X is a locally compact and separable (why?) metric space, A is merely closed.

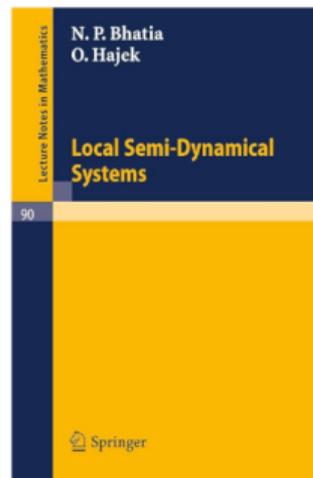

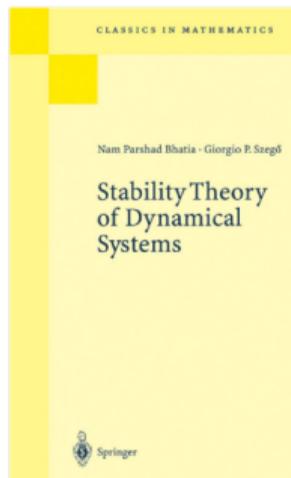

(R) X is a locally compact Hausdorff space, A is closed with ∂A compact (why?).

The space in (R) is more general than the space in (L), but the attractor is not... what could possibly be 'the most general' setting? (👉)

Topological properties of *compact* attractors

Let x_* be GAS under some smooth ODE $\dot{x} = f(x)$, then, the *basin of attraction* $B(x_*)$ is a *contractible* set, e.g., there is no smooth ODE such that $q_* \in \mathbb{S}^1$ is GAS.

How to generalize beyond points, that is, to generic (asymptotically stable!) *compact* attractors?

The set $A \subseteq X$ is a *weak deformation retract* when any open neighbourhood U of A contains a *strong deformation retract* (say, V) of X .

Theorem (Moulay and Bhat [MB10, Thm. 5])

If a compact set A is invariant and asymptotically stable under a semiflow, on a locally compact Hausdorff space, then, A is a weak deformation retract of $B(A)$. (Shown using Lyapunov functions.)

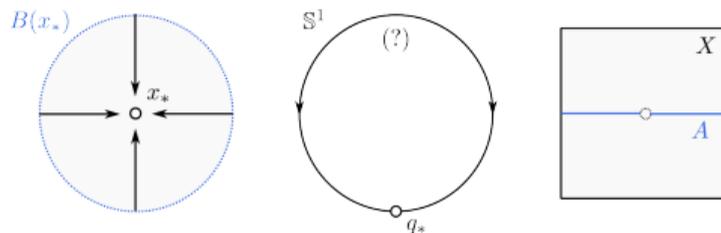

Question: “Precisely when do we have a *strong* deformation retract?”

Topological properties of *compact* attractors

Theorem (Moulay and Bhat [MB10, Thm. 5])

If a compact set A is invariant and asymptotically stable under a semiflow, on a locally compact Hausdorff space, then, A is a **weak deformation retract** of $B(A)$. (Shown using Lyapunov functions.)

Question: “Precisely when do we have a **strong** deformation retract?”

Answer (sketch):

When for a closed subset $A \subseteq X$ there is an open neighbourhood $U \subseteq X$ of A such that A is a “...” retraction of U , then A is a *neighbourhood retract*, of type “...”.

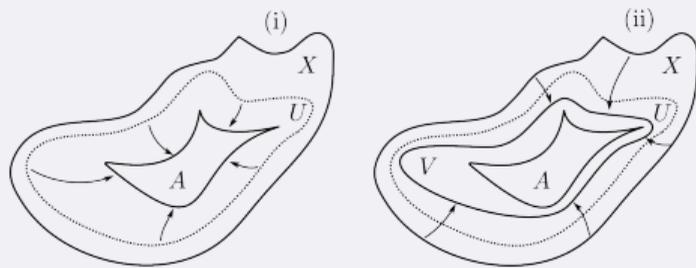

If, (i) $A \subseteq X$ is a *neighbourhood deformation retract*,
and (ii) A is a *weak deformation retract* of X ,
then, A is a *deformation retract* of X .

Thus, by [MB10], A being a neighbourhood deformation retract of $B(A)$ implies $A \simeq_h B(A)$.
We will appeal to *cofibrations* to capture this.

Answer (sketch):

When for a closed subset $A \subseteq X$ there is an open neighbourhood $U \subseteq X$ of A such that A is a “...” retraction of U , then A is a *neighbourhood retract*, of type “...”.

If, (i) $A \subseteq X$ is a *neighbourhood deformation retract*,

We will appeal to **cofibrations** to capture this.

Topological properties of compact attractors cont'd.

Theorem (Cofibration and compact attractors, WJ 24.⁷)

Let M be a locally compact Hausdorff space and let $A \subseteq M$ be a compact, asymptotically stable attractor with basin of attraction $B(A)$ (under some semi-dynamical system). Then, A is a strong deformation retract of $B(A)$ $\iff \iota_A : A \hookrightarrow B(A)$ is a cofibration.

Example (Warsaw circle, dynamics \implies topology):

The Warsaw circle W^1 can be an attractor with an annular neighbourhood $A \subset \mathbb{R}^2$ as $B(W^1)$ [Has79]⁸. However, W^1 cannot be a strong deformation retract of A since $\pi_1(W^1) \cong 0$ while $\pi_1(S^1) \cong \mathbb{Z}$. Hence, $\iota_{W^1} : W^1 \hookrightarrow A$ cannot be a cofibration.

Topological properties of closed attractors.

Compact attractors are well-understood [Aki93], what about attractors that are **merely closed**?

Can we just do the same as before? No.

Lin, Yao and Cao provide an interesting closed attractor [LYC22, Ex. 22], in correcting work by Wilson. (X, d) a metric space with $X := \mathbb{R}^2 \setminus \{(1, 0)\}$ and $A = S^1 \cap X$. Could U be a metric neighbourhood?

Here, $A \hookrightarrow B(A)$ is a cofibration (tubular neighbourhood), but $A \cong \{*\}$ while $B(A) \cong S^1 \vee S^1$.

What *can* be said?

Topological properties of closed attractors.

Compact attractors are well-understood [Aki93], what about attractors that are **merely closed**?

Can we just do the same as before? No.

Lin, Yao and Cao provide an interesting closed attractor [LYC22, Ex. 22], in correcting work by Wilson.

(X, d) a metric space with $X := \mathbb{R}^2 \setminus \{(1, 0)\}$ and $A = \mathbb{S}^1 \cap X$. Could U be a metric neighbourhood?

Here, $A \hookrightarrow B(A)$ is a cofibration (tubular neighbourhood), but $A \cong \{*\}$ while $B(A) \cong \mathbb{S}^1 \vee \mathbb{S}^1$.

What *can* be said?

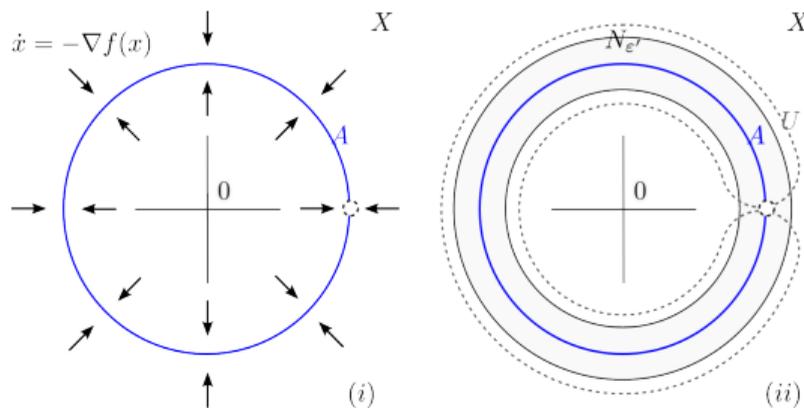

Topological properties of closed attractors.

Topological properties of closed attractors cont'd.

The solution is rather technical⁹. We provide some pointers. (Heavily inspired by Auslander, Bhatia, ...)

(i) The metric and topological definitions of stability are *not* equivalent (why?).

Let $N_\varepsilon(A; d) := \{x \in X \mid d(x, A) < \varepsilon\}$.

(1): A is *uniformly stable* when for each $\varepsilon > 0$ there is a $\delta(\varepsilon) > 0$ such that

$\{\varphi^t(x) \mid x \in N_{\delta(\varepsilon)}(A; d), t \geq 0\} \subseteq N_\varepsilon(A; d)$.

(2): A is a *uniform attractor* if there is some $\alpha > 0$, and for any $\varepsilon > 0$ a $T(\varepsilon) > 0$ such that

$\{\varphi^t(x) \mid x \in N_\alpha(A; d), t \geq T(\varepsilon)\} \subseteq N_\varepsilon(A; d)$.

Combine (1) and (2): *uniform asymptotic stability* (see [BS70] for the Lyapunov theory).

(ii) Again, we employ NDRs, but now, the neighbourhood that deformation retracts onto A must contain some *metric* neighbourhood.

(iii) We formalize this using *filters* (inspired by Auslander[†] [Aus77]) and ' \mathcal{F} -cofibrations'.

Theorem (Cofibration and closed attractors, WJ 25.¹⁰)

Let A be a closed subset of a separable, locally compact metric space (X, d) . Suppose that A is uniformly asymptotically stable, with $B(A)$ containing $N_\varepsilon(A; d)$ for some $\varepsilon > 0$. Then, A is a **strong deformation retract** of $B(A)$ if and only if $\iota_A : A \hookrightarrow B(A)$ is a \mathcal{F}_d -cofibration.

What about a topological definition of stability? Assert stability using a *single continuous* Lyapunov function $V : X \rightarrow \mathbb{R}_{\geq 0}$? $\mathbb{R}_{\geq 0}$ is second countable.. $x \mapsto d(x, A)$ allows for getting a grip on metric neighbourhoods using a *single continuous* function.

Answer to $A \not\approx_h B_u(A)$ (circular example):

Although one can 'see $A \not\approx_h B_u(A)$ ', our results tell us that for A to be a strong deformation retract of $B_u(A)$, we must have

$$\iota_U \simeq_h \iota_A \circ r,$$

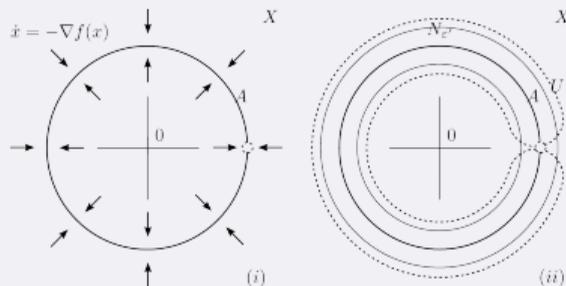

for $r : U \rightarrow A$ a retract, U a metric neighbourhood of A and $\iota_U : U \hookrightarrow X$, $\iota_A : A \hookrightarrow X$ inclusion maps.

Then, we look at the factorization:

$$\pi_1(U) \xrightarrow{\iota_U^*} \pi_1(B_u(A)) = \pi_1(U) \xrightarrow{r_*} \pi_1(A) \xrightarrow{\iota_A^*} \pi_1(B_u(A))$$

which clearly fails, hence we recover the conclusion.

Answer to $A \not\approx_h B_U(A)$ (circular example):

Although one can 'see $A \not\approx_h B_U(A)$ ', our results tell us that for A to be a strong deformation retract of $B_U(A)$, we must have

$$\iota_U \simeq_h \iota_A \circ r,$$

for $r : U \rightarrow A$ a retract, U a metric neighbourhood of A and $\iota_U : U \hookrightarrow X$, $\iota_A : A \hookrightarrow X$ inclusion maps.

Then, we look at the factorization:

$$\pi_1(U) \xrightarrow{\iota_{U*}} \pi_1(B_U(A)) = \pi_1(U) \xrightarrow{r_*} \pi_1(A) \xrightarrow{\iota_{A*}} \pi_1(B_U(A))$$

which clearly fails, hence we recover the conclusion.

So, even for closed attractors, we are starting to understand when $A \simeq_h B_u(A)$,
can we use this?

Hybrid control and homology (as pioneered in [Bar23]).

Given these results on *strong deformation retracts*, we can *link topological properties* of A and $B(A)$.

Suppose we want to globally stabilize a set A on X , i.e., given $\dot{x} = f(x, u)$ on (X, d) find some C^0 feedback $x \mapsto \mu(x)$. 'How far is X from $B(A)$?' Can it be done, do we need *discontinuous* feedback?

Let there be a set of 'cuts' C such that $A \hookrightarrow X \setminus C$ is a \mathcal{F}_d -cofibration and A is uniformly asymptotically stable on $X \setminus C$, then, $A \simeq_h X \setminus C$.

Let C be c -dimensional and regular enough, it follows from *Thom's isomorphism* that:

$$\cdots \rightarrow H^{n-c}(C; \mathbb{Z}) \rightarrow H^n(X; \mathbb{Z}) \rightarrow H^n(A; \mathbb{Z}) \rightarrow H^{n-c+1}(C; \mathbb{Z}) \rightarrow \cdots \quad (3)$$

Then, from (3), we obtain directly the following inequalities:

$$\begin{aligned} \beta^n(X) &\leq \beta^{n-c}(C) + \beta^n(A) \\ \beta^n(A) &\leq \beta^n(X) + \beta^{n-c+1}(C) \\ \beta^{n-c}(C) &\leq \beta^{n-1}(A) + \beta^n(X), \end{aligned} \quad (4)$$

where $\beta^i(\cdot) = \text{rank}(H^i(\cdot; \mathbb{Z}))$, i.e., (4) understood as topological constraints on C . (👉 fun.)

Hybrid control and homology (as pioneered in [Bar23]).

Thinking of 'canonical systems' ($\dot{x} = -x$) can help, shift the focus to transformations, not direct parametrizations (there is more Koopman-related work).

Cofibrations help in capturing homotopy equivalence of A and $B(A)$ (Did not discuss: *shape equivalence*.) Can we sharpen topological constraints on the set of cuts (include the embedding $A \hookrightarrow X$)?

Lyapunov theory has been the key tool in all results. Can we discover more transformations? More homotopy results?

Art of the state... (Sepulchre)
